1 DOMjudge

1.1 Overview

DOMjudge is the online judge we use to host contests.

Go to <http://domjudge2.cs.illinois.edu/team/> and enter your assigned credentials to access the contest dashboard.

The screenshot shows the DOMjudge overview page. At the top, there are tabs for 'overview', 'problems', and 'scoreboard'. The 'overview' tab is active. Below the tabs, there is a table showing the top teams. The 'Example team' is highlighted. Below this, there is a table of submissions. The table has columns for 'time', 'problem', 'lang', and 'result'. The submissions are listed in descending order of time. The 'Example team' has several submissions, some of which are 'CORRECT' and some are 'WRONG-ANSWER'. On the right side, there is a sidebar with 'Clarifications' and 'Clarification Requests'. The 'Clarifications' section shows a list of questions and answers. The 'Clarification Requests' section shows a list of requests.

On this page, you can

- view problem statements by clicking the problem names.
- view the list of past submissions and verdicts (more about verdicts later).
- upload your solution.
- view and request clarification to problems.

1.2 Scoreboard

By clicking the **scoreboard** link on the top of the overview page, you can access the scoreboard page.

The screenshot shows the DOMjudge scoreboard page. At the top, there are tabs for 'overview', 'problems', and 'scoreboard'. The 'scoreboard' tab is active. Below the tabs, there is a table showing the final standings of teams. The table has columns for 'RANK', 'TEAM', 'SCORE', and a grid of colored circles representing the results for each problem. The teams are ranked by the number of problems solved. The 'Example team' is highlighted. The table shows 16 teams in total.

We are following the standard ACM-ICPC rule:

Teams are ranked according to the most problems solved. Teams who solve the same number of problems are ranked first by least total time and, if need be, by the earliest time of submittal of the last accepted run.

The total time is the sum of the time consumed for each problem solved. The time consumed for a solved problem is the time elapsed from the beginning of the contest to the submittal of the first accepted run plus 20 penalty minutes for every previously rejected run for that problem. There is no time consumed for a problem that is not solved.

2 Solving a Problem

In competitive programming contests, solving a problem takes the following three steps:

1. Read the Problem Statement
2. Write Code and Test
3. Submit Your Code to the Judge

2.1 Reading the Problem Statement

In most programming contests, the problem statement usually consists of several parts:

<p>A particle has initial velocity and acceleration. If its velocity after certain time is v then what will its displacement be in twice of that time?</p>	<p>Problem Description: tells you what to do; might contain background stories</p>
<p>Input</p> <p>The input will contain two integers in each line. Each line makes one set of input. These two integers denote the value of v ($-100 \leq v \leq 100$) and t ($0 \leq t \leq 200$) (t means at the time the particle gains that velocity)</p>	<p>Input Specification: Format, Meaning & Range</p>
<p>Output</p> <p>For each line of input print a single integer in one line denoting the displacement in double of that time.</p>	<p>Output Specification: how you should print the results out</p>
<p>Sample Input</p> <pre>0 0 5 12</pre> <p>Sample Output</p> <pre>0 120</pre>	<p>Sample Input & Output: one or more groups of (weak) testing data that helps you understand the problem and debug your code</p>

In addition, a problem might also have a time limit and a memory limit your program can reach at maximum:

<p>F. To Play or not to Play</p> <p>time limit per test: 2 seconds</p> <p>memory limit per test: 256 megabytes</p>

In conclusion, you need to read the problem statement, extract useful information, understand and model the problem it asks you to solve, and think of the appropriate algorithms and data structures you will use later.

It is also extremely important to pay attention to the range of the input data, as different ranges may indicate completely different algorithms and difficulty levels for the problem.

2.2 Writing Code and Testing

2.2.1 Basics

You write your code, compile it (for compiled languages), and test it on your local machine.

All your code should be contained in a single source file, no matter what language you use.

Your program should read the data from standard input, solve the problem specified in the statement, and print the results to standard output (unless otherwise specified).

Make sure you test your solution against the sample inputs and outputs, as it is a bare minimum requirement for your solution to get accepted by the judge.

2.2.2 Exit Code of Your Program

No matter what language you use, your program should always have zero as the exit code.

A non-zero exit code will make the judge think your program terminated in an abnormal way, and will not accept your solution even if your output is correct.

C++ users, please "return 0" manually in your main function. Python and Java users, as long as you do not call some system function to explicitly return a non-zero value, you should be fine.

2.2.3 Starter Code for C++, Java and Python

The following programs read an integer from the input, multiply it by 2 and print it to the output. This should teach you what a minimal solution should look like and how to do basic IO.

```
// C++
int main() // do not use void main!!!!
{
    int x;
    cin >> x;
    cout << x*2 << endl;
    return 0;
}
```

```
// Java
```

```
// do not specify any packages!!!
```

```
import java.io.*;
import java.util.*;
```

```
public class Main { // "Main" should be used for most online judges
    public static void main(String[] args) {
        Scanner sc = new Scanner(System.in);

        int x = sc.nextInt();
        System.out.printf("%d\n", x);
    }
}
```

We highly recommend Python users to select PyPy for Python solutions because PyPy is significantly faster than the standard Python Implementation.

```
# python3
x = int(input())
print(x*2)
```

```
# python2
x = int(raw_input())
print x*2
```

3 Understanding The Judge's Verdicts

After your submission is received, the judge will run your program against it's own comprehensive test cases, which are not visible to you, and give you a verdict.

The judge's verdict can be one of the following types:

- **CORRECT** The submission passed all tests: you solved this problem!
- **COMPILER-ERROR** There was an error when compiling your program. On the submission details page you can inspect the exact error.
- **TIMELIMIT** Your program took longer than the maximum allowed time for this problem. Therefore it has been aborted. This might indicate that your program hangs in a loop or that your solution is not efficient enough.
- **RUN-ERROR** There was an error during the execution of your program. This can have a lot of different causes like division by zero, incorrectly addressing memory (e.g. by indexing arrays out of bounds), trying to use more memory than the limit, etc. Also check that your program exits with exit code 0!
- **NO-OUTPUT** Your program did not generate any output. Check that you write to standard out.
- **OUTPUT-LIMIT** Your program generated more output than the allowed limit. The output was truncated and considered incorrect.
- **WRONG-ANSWER** The output of your program was incorrect. This can happen simply because your solution is not correct, but remember that your output must comply exactly with the specifications of the jury.
- **TOO-LATE** Bummer, you submitted after the contest ended! Your submission is stored but will not be processed anymore.

4 Working With Command Line Prompt

If you are using an EWS machine, your preferred IDE or GUI editor may not be available. In this case, you need to switch to a text editor (vim, emacs, sublime etc.), compile, run and test your code using the command line prompt.

4.1 Compile and Run Your Code

4.1.1 C++

```
# suppose src.cpp is your source file, use g++ to compile it
g++ src.cpp
# this will generate an executable file a.out, and you can run it by calling
./a.out
```

```
# you can use the -o option to specify the name of the executable
# otherwise, the name defaults to "a.out"
g++ src.cpp -o my_program
```

```
# if you want to use c++11, make sure to add the following option
g++ -std=c++11 src.cpp
```

4.1.2 Java

```
# suppose Main.java is your source file, use javac to compile it
javac Main.java
# this will generate a file named "Main.class" under the same directory
# then use java to run it
java Main
```

4.1.3 Python

```
# python is an interpreted language
# use python/python3 to run your code directly
python src.py
python3 src.py
```

4.2 Input/Output Redirection

Bash allows you to redirect the input and the output of a process. This is very useful for testing as it can save you from typing the input data every time.

```
# suppose you write your input data to a text file input.txt
# then you can use < to read the data from the file and feed it to a program
my_program < input.txt

# use > to write the output of a program to a file
my_program > output.txt

# use | to pipe the output of a program to another program
ls | grep '.cpp'
```

4.3 Other Useful Commands

```
# change the current directory to xxx
cd xxx
# the path can contain .. which means the "parent directory"
cd ../yyy

# display all the files and sub directories under the current directory
ls

# delete the file a.cpp
rm a.cpp
# delete the directory "mydir" recursively
rm -rf mydir
```
